Acknowledgements

In addition to the work of the members of the NE-35 Technical Committee who are listed on the inside front cover, the editors are grateful for the dedicated assistance of Mrs. Josephine Bloom and Mrs. Frances Van Kirk who spent many long hours in preparing and checking the tables and in typing and proofreading the manuscript.

Final thanks must go to the cooperative climatological observers of the U. S. Weather Bureau for taking the observations on which most of the work of the NE-35 Committee is based.

THE CLIMATE OF THE NORTHEAST

GROWING DEGREE DAYS

B. E. Dethier and M. T. Vittum

Introduction

Growing degree days, sometimes called "heat units," "effective heat units," or "growth units," are an arithmetic accumulation of daily mean temperatures above a certain threshold temperature. They are a simple means of relating plant growth, development, and maturation to environmental air temperature. Different species of plants have different base or threshold temperatures below which they theoretically do not grow. At temperatures above this base or threshold value, the amount of plant growth is approximately proportional to the amount of heat or temperature accumulated. The base temperatures used in this bulletin, 40° and 50° F, correspond closely to the generally accepted values of the base temperatures for several economically important plants:

Spring Wheat	37 to 40° F
Canning Peas	40° F
Oats	43° F
Potatoes	45° F
Sweet Corn, Snap Beans	50° F
Lima Beans, Tomatoes	50° F
Field Corn	55° F

The growing degree day value for any day is easily obtained by subtracting the appropriate base or threshold temperature for the specific crop from the mean temperature. Thus, on a day with a maximum of 65° and a minimum of 55°, the mean temperature would be 60°. The growing degree days for peas, with a 40° base or threshold, would be 60 (the mean) minus 40 (the base), or 20. The growing degree days for snap beans or sweet corn would be 60 (the mean) minus 50 (the base), or 10.

The growing degree days, to any base, can be computed each day from daily temperatures, and can be accumulated over the course of the growing season. Note, however, that negative values are ignored in summation of growing degree days. Thus, zero is the value assigned to any day when the mean temperature is below the base or threshold value.

The amount of plant growth is approximately proportional to the amount of heat or temperature accumulated above the base. For each species of plant, and for different varieties, maturity is reached when the growing degree days have accumulated to a certain sum. The various pea varieties, for example, require a range from about 1,200 to 1,800 growing degree days. This means of reckoning the time of maturity has been applied by the canning industry, since the planting dates of peas and other field crops can be scheduled to maintain an orderly supply for processing. The heat unit system is also helpful in selecting crop varieties appropriate to different farming areas. The method has also been used in scheduling the work of fruit orchards. Since insect emergence and development also respond to temperature, heat sums have been utilized to predict epidemic outbreaks of insects.

The list of references of page 14 may be consulted for more detailed information and instructions on the application of growing degree days and on the various refinements that have been suggested for the basic system outlined above. It is a useful system but has two main flaws. It over simplifies the complex temperature response of plants, and it does not take into account the many other environmental factors affecting plant growth. It does, however, serve a very practical need, and knowledge of the agricultural climate of an area is incomplete without some idea of the growing degree days normal in that area. This bulletin is accordingly presented as a source of basic information for home gardeners, nurserymen, growers, processors, and research, teaching, and extension specialists to be used or adapted according to individual preferences and requirements.

Explanation of Tables and Maps

Climatological Weeks

The growing degree day values in this bulletin are averages for 141 stations over the 30-year period 1926-1955, with exceptions as explained later. The data are presented according to weeks of the climatological year, which is outlined in Table 1. Data for Week 53 (February 28 and 29) are omitted. Data for the 52 complete weeks from March 1 through February 27 are given in the tables.

Station Locator Map

Figure 1 shows the geographical distribution of the stations used in this bulletin. The number assigned to each station in the Weather Bureau network is plotted next to the corresponding station circle. The first digit of these station numbers increases from "0" or "1" to "9" according to the alphabetical positions of the initial letter of the station's name. In New York State, for example, Albany is numbered 0047 and Watertown is 9000. Between these, Fredonia is 3033, Morrisville 5512, Setauket 7633, etc.

		53	Feb. 28 - Feb. 29

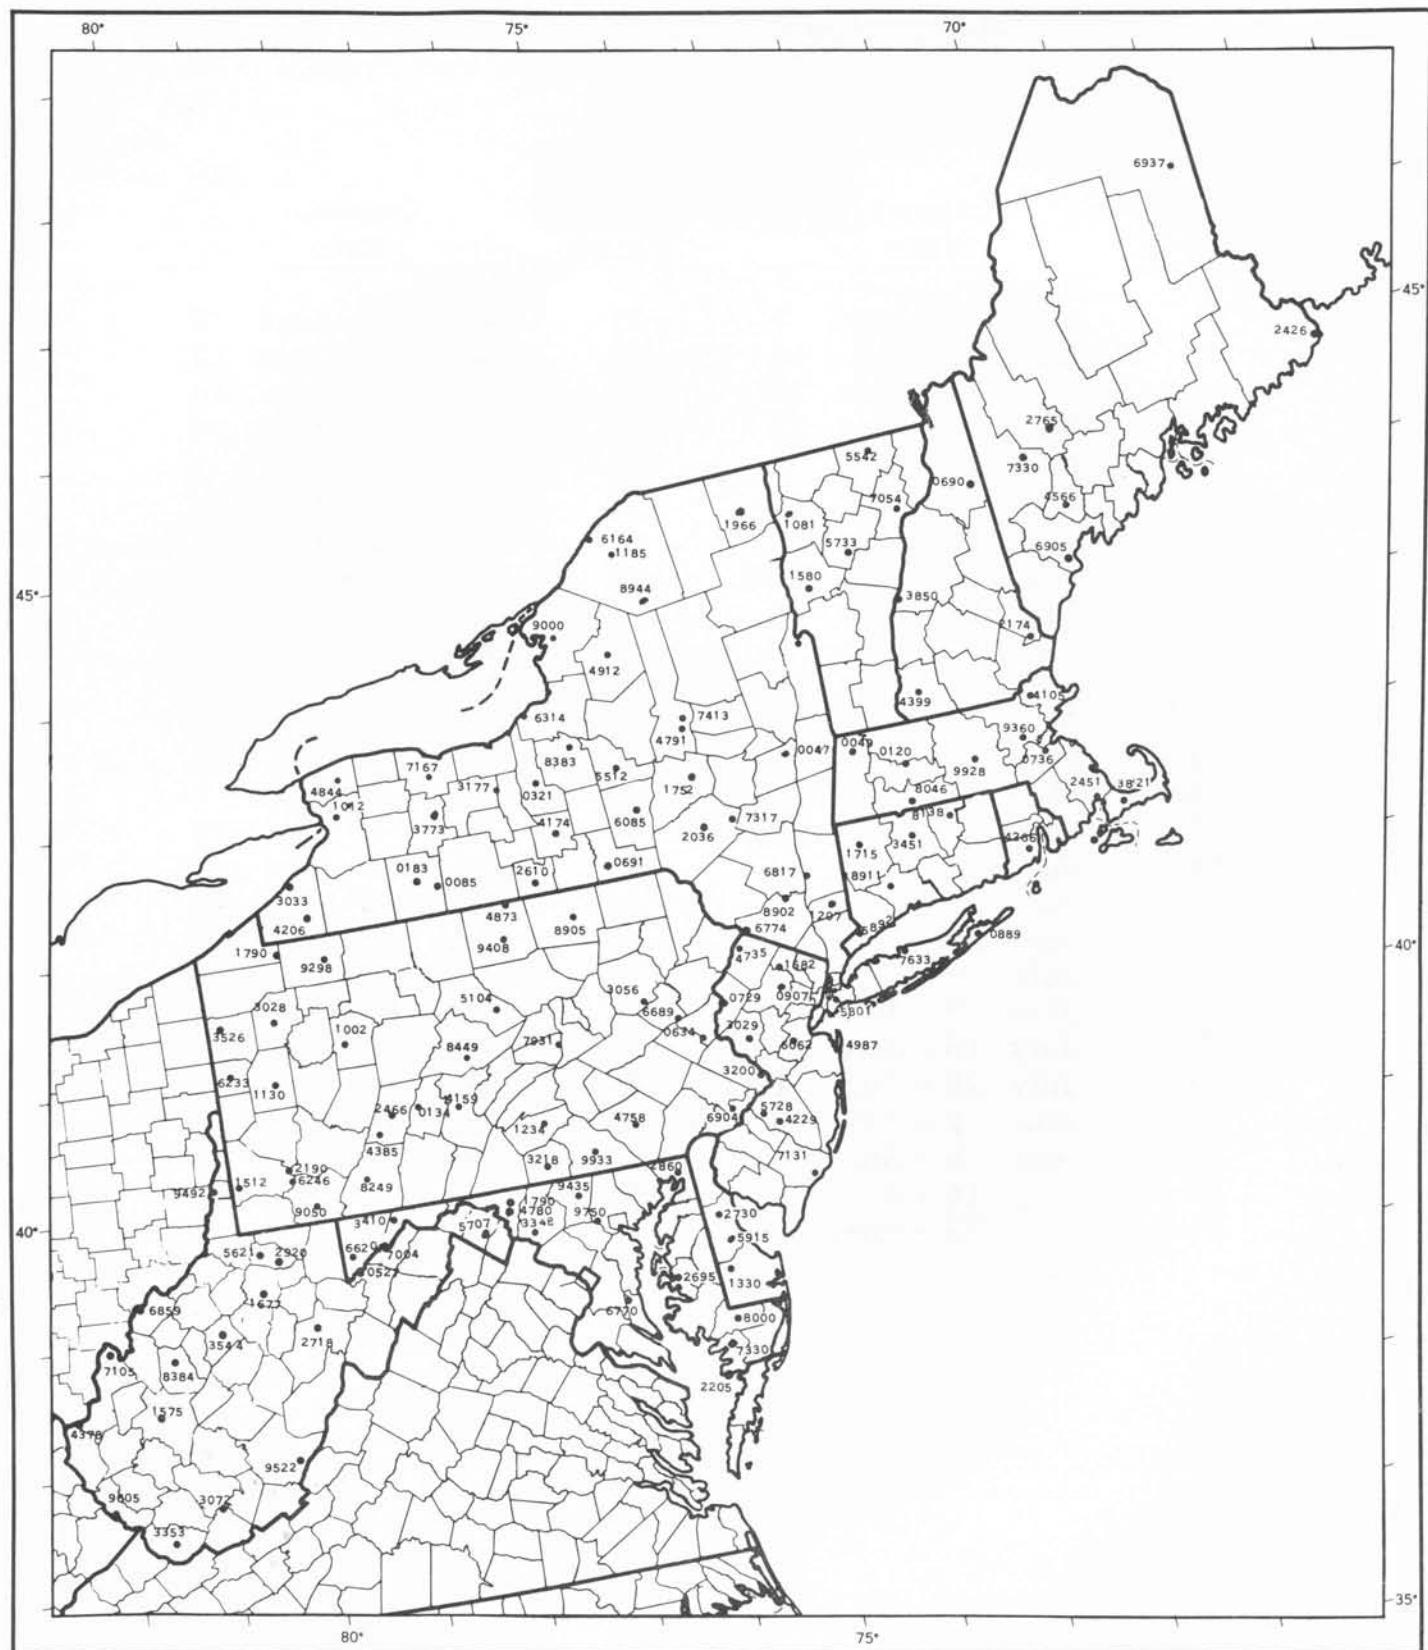

Figure 1. Station-locator map.

The user of this bulletin can find the location of any station shown in Figure 1 by looking up its number in the second column of Table 2, remembering that a low number will be found near the beginning of the list for each state, a high number near the end. Further information on the stations used in this bulletin will be found in the substation history publications of the U. S. Weather Bureau, No. 27 in the list of references, page 14.

Cumulative Growing Degree Days

Table 2 presents, for the 141 locations, the cumulative growing degree days for both 40° and 50° base, for the first 10-, 20-, and 30-week periods of the climatological year as well as the total for the 52-week year. Locations are grouped by states and are arranged alphabetically within each state. Almost all the locations are stations in the cooperative climatological network of the U. S. Weather Bureau, exceptions being regular Weather Bureau stations located at commercial airports. The locations are identified by name, station number, county, elevation, latitude, and longitude. In some cases, where the station is outside the town after which it is named, its distance and direction in miles from the Post Office is indicated. For instance, "Bridgeville 1NW" means that the temperature observing station is situated approximately one mile northwest of the Bridgeville Post Office. The number of years that were examined in order to obtain the information on the growing degree days is also classified for each station.

Figures 2-7 are "contour" maps which outline areas of equal accumulated growing degree days for 20-, 30-, and 52-week accumulations for 40° and 50° . Here the reader can obtain a visual indication of geographical areas in the Northeast which have similar growing degree day conditions.

Weekly Growing Degree Days, Base 40°

Table 3 lists the mean weekly accumulation of growing degree days above a base temperature of 40° for each of the 141 stations. In addition to the weekly total accumulation, the standard deviation ("s") of this figure is given in the adjoining column. The standard deviation indicates the amount of variation that can be expected from one year to another. One can expect that 68 per cent of the time, or about 2 years out of 3, the growing degree accumulation for any given week will be the mean given in Table 3 plus or minus the standard deviation adjacent to this mean. Thus, for Week 20 at Cream Hill, Connecticut, one would expect a mean growing degree accumulation of 208, plus or minus 22. This means that two-thirds of the time, residents of Cream Hill could expect growing degree days for this week to be between 186 and 230.

About 95 per cent of the time, or 19 years out of 20, the growing degree day accumulation will be the mean plus or minus twice the standard deviation. Thus, residents of Cream Hill could expect that only once in 20 years would the growing degree days for Week 20 fall outside of the range 164 and 252.

Mean growing degree days and the mean plus or minus 1 standard deviation for Geneva, New York, are plotted in Figure 8 to show how one can use the information in Table 3. Two-thirds of the time one would expect growing degree day accumulation for any specific week at Geneva to fall within the dotted area.

Weekly Growing Degree Days, Base 50°

Table 4 is similar to Table 3, except the base temperature is 50° instead of 40°. A base or threshold temperature of 50° is normally used for warm-season crops such as snap beans, sweet corn, and tomatoes.

Estimating Growing Degree Days

If the 141 stations used in this study were uniformly distributed throughout the Northeast, there would be one station for every 1,394 square miles. Since most of the population does not live in close proximity to one of these stations, it was desirable to devise a method of estimating growing degree days for other stations. There are many more weather stations in the Northeast, but because their records were incomplete or because the location of their instruments has been changed, they were not used in this study. If multiple regression equations could be developed from the basic station network an approximation of growing degree days could be obtained for additional stations, thereby extending the usefulness of this bulletin.

Six stepwise multiple regression equations were obtained by computer for the sum of the first 20 and 30 weeks of the year, and for the entire year for both 40° and 50° bases. The parameters investigated included latitude, station elevation, mean annual temperature, mean January temperature, mean July temperature, length of freeze-free period as well as the starting and ending dates of the freeze period. The mean annual and mean January or July temperatures gave equations which explained approximately 95 per cent of the variance. The following equations will give an estimate of the growing degree days with an error of less than 5 per cent in most cases:

Growing Degree Days, Base 40°

$$\begin{array}{lll} Y_{20} = -4158 + 149X_1 - 33X_2 & R^2 = 95 \\ Y_{30} = -6241 + 109X_1 + 71X_3 & R^2 = 96 \\ Y_{52} = -8294 + 165X_1 + 71X_3 & R^2 = 97 \end{array}$$

Growing Degree Days, Base 50°

$$\begin{array}{lll} Y_{20} = -3883 + 123X_1 - 33X_2 & R^2 = 88 \\ Y_{30} = -6924 + 69X_1 + 84X_3 & R^2 = 97 \\ Y_{52} = -8089 + 94X_1 + 87X_3 & R^2 = 97 \end{array}$$

where,

Y_{20} , 30 , and 52 = G. D. D. accumulations for the first 20-, 30- and 52-week periods of the climatological year.

X_1 = Mean annual temperature

X_2 = Mean January temperature

X_3 = Mean July temperature

and, R^2 = Multiple correlation coefficient.

Approximations of the growing degree days can be determined from figures 9, 10 and 11. A more accurate estimate can be obtained by using the appropriate equations. These equations were developed from the data in Table 2 and have not been tested for stations outside of the Northeast.

Source of Data

Directors of the State Agricultural Experiment Stations in the 12 Northeastern States appointed a Regional Technical Committee in 1956. This committee initiated a Regional Research Project, NE-35, to study the application of climatology to agriculture in the Northeast. The participating State Experiment Stations and Federal agencies, and the individuals representing these agencies, are listed (on the inside of the front cover).

The first objective of the committee has been the preparation of a series of publications dealing with various climatological factors affecting agriculture in the region. Bulletins on low temperature or freeze probabilities (7), weekly rainfall probabilities (3), and heating degree day probabilities (4), have already been published. Bulletins on temperature probabilities, drought probabilities, and heating degree days are presently being prepared by members of the committee. Bulletins on probabilities of extreme temperature, extreme precipitation, and runs of consecutive hot or cold and wet or dry days will be prepared in the future.

The NE-35 Committee selected approximately 160 climatological stations in the Northeast for analysis according to a standard regional plan. The 30-year period 1926-1955 was chosen as the standard period for analysis of the records. The stations were selected in an effort to represent the major climatological and agricultural divisions of the Northeast. Stations with records that were not complete over the 1926-1955 period, and those that had undergone major changes in location, were avoided except in those areas where no better stations were available. Only the 141 stations with at least 25 years of temperature observations were used in this growing degree day bulletin. The number of years analyzed for each of these stations is given in Table 2.

From 1948 on, the daily records of all stations were already available on punched cards through the climatological data processing program of the U. S. Weather Bureau. Cooperative agreements between the Bureau and the state agencies resulted in punching on cards the records prior to 1948. The NE-35 Committee decided upon a number of climatological studies to be made using the punched card records, and programs were developed to perform the required analyses using high speed electronic computers and auxiliary equipment.

The program produced the mean weekly growing degree day accumulation for each station and the standard deviation of this mean. The assumption was made that the growing degree day distributions are normally distributed. Thus, the probabilities were computed using average dates and their standard deviations.
