Modeled vertically integrated smoke fits the location of the observed smoke.

Conclusions

- Southerly wind flow, combined with temperatures barely over 80 degrees, is not the usual pattern for an ozone exceedance;
- Although a smoke plume from western Canada had been meandering across the country during recent days, it had not yet reached the ground and affected air quality;
- Ozone levels were forecast to be borderline MODERATE for this day;
- The image from the New Haven ceilometer, illustrates aerosols from smoke at upper levels of the atmosphere, which descended to the surface by 1:00pm;
- Back trajectories at 3 levels, show air originating from within the analyzed smoke plume.
- Since the NOAA model had actually decreased the ozone forecast, it was the preferred model - but it did not include smoke chemistry!

Ozone Event Analysis: June 27-29, 2019

Michael Geigert

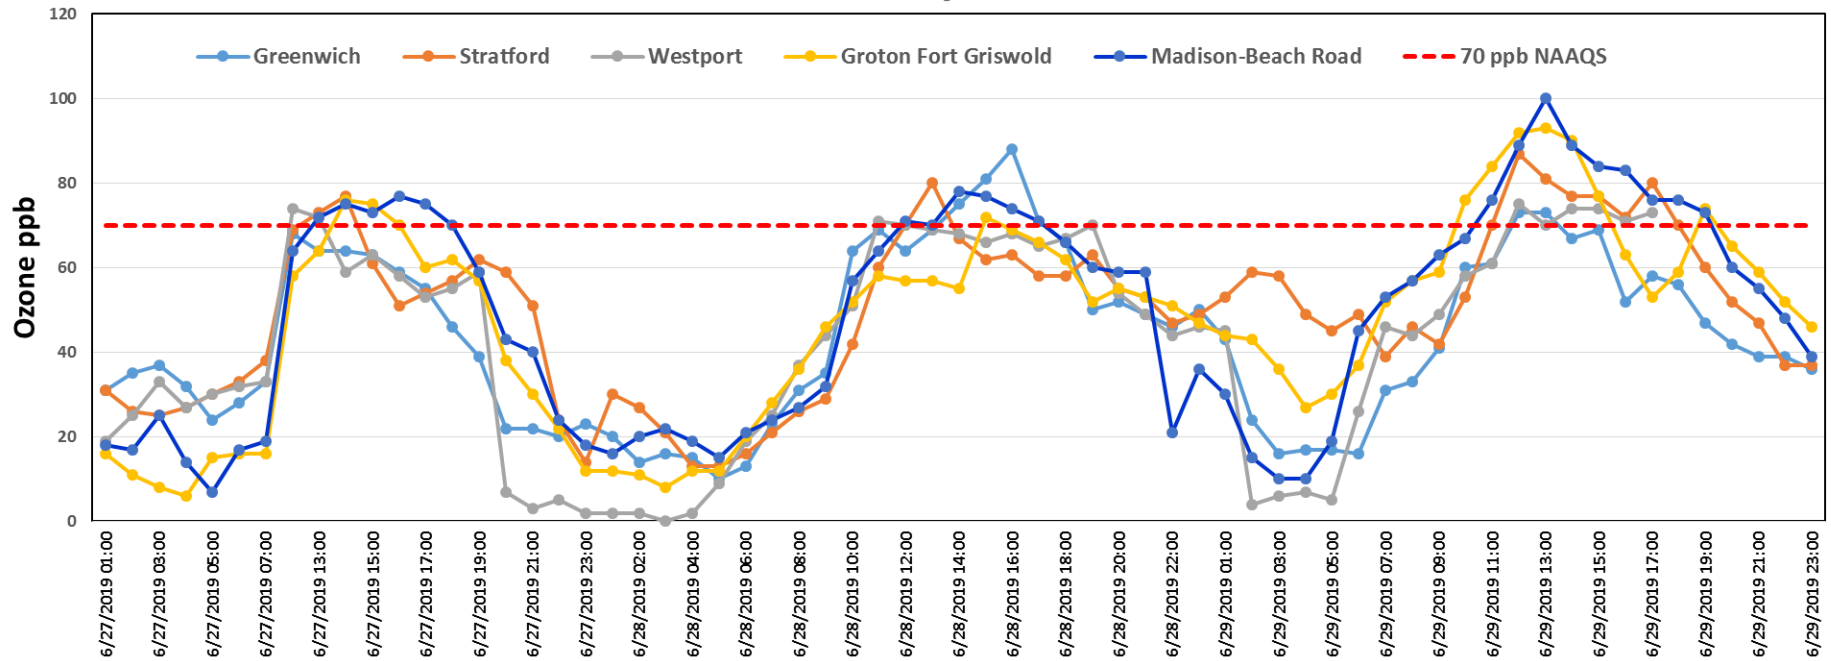

June 27-29, 2019: 8-hour Ozone Maximums

June 27-29, 2019 Hourly Ozone

June 27-29, 2019 Hourly Ozone Connecticut

- Only the coastal monitors had exceedances, with Madison peaking on June 29th.

Maximum 24-hr Temperature

- Temperatures reached the upper 80's to low 90's along the I-95 corridor, which provided conditions for ozone production.

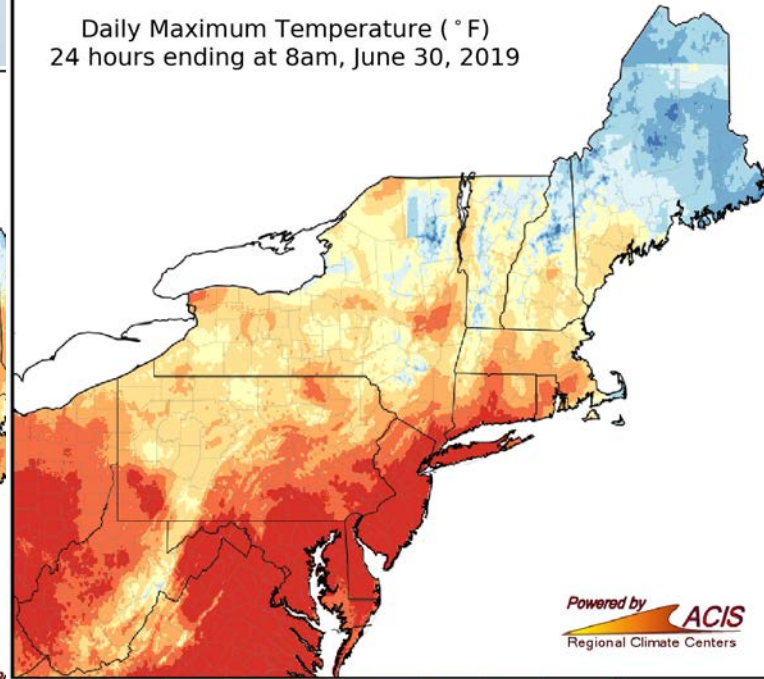

Daily Maximum Temperature (°F)
24 hours ending at 8am, June 28, 2019

Daily Maximum Temperature (°F)
24 hours ending at 8am, June 29, 2019

Daily Maximum Temperature (°F)

Powered by
ACIS
Regional Climate Centers

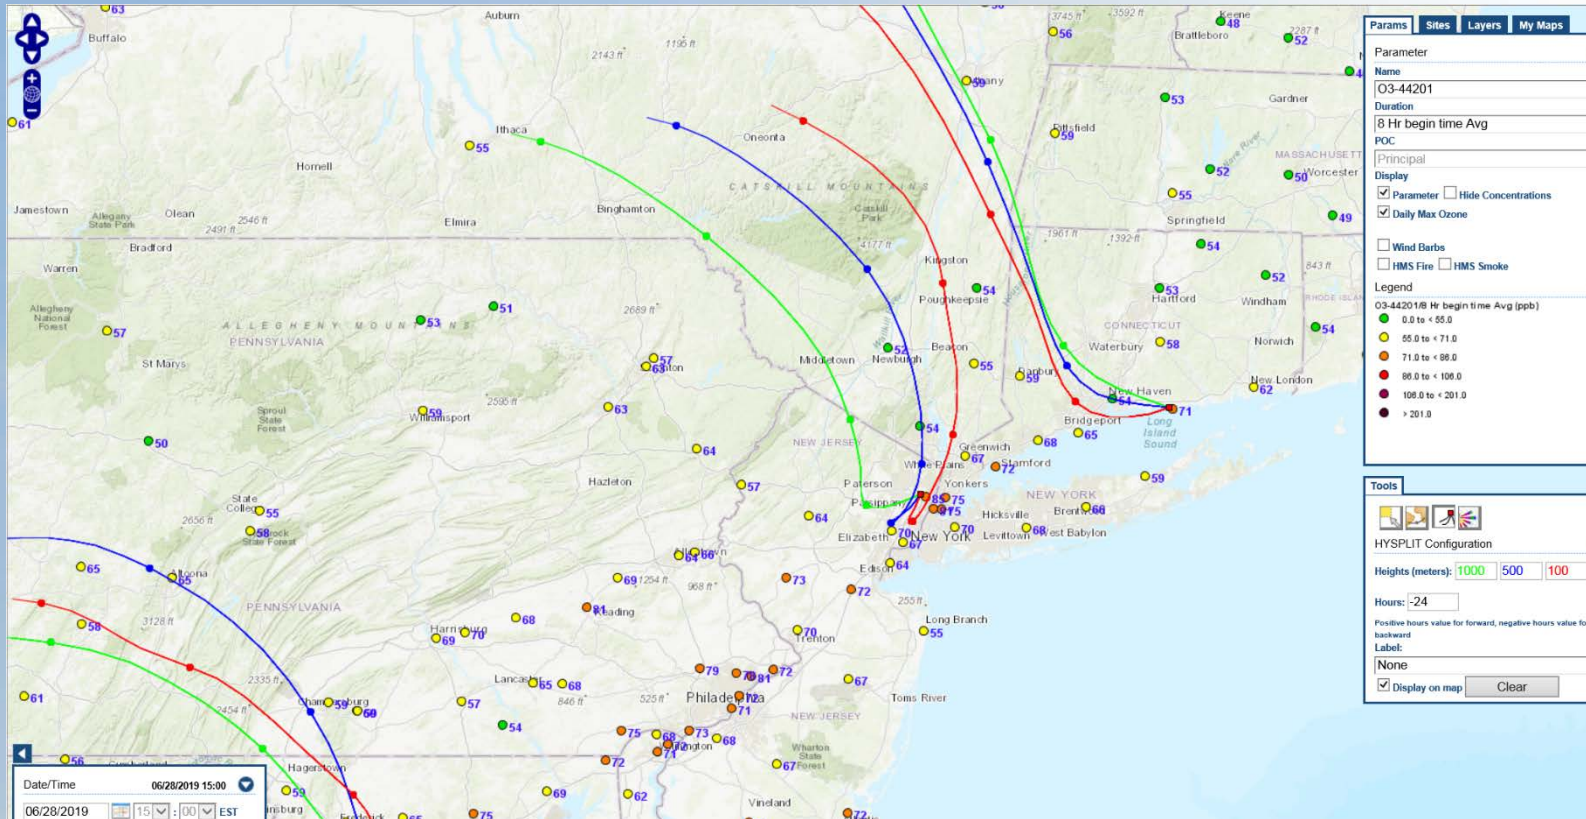

June 27, 2019 Back Trajectories

- Surface winds were light from the north but turned southwest late in the day. This advected ozone from LIS into coastal Connecticut. Upper air winds were from the northwest.

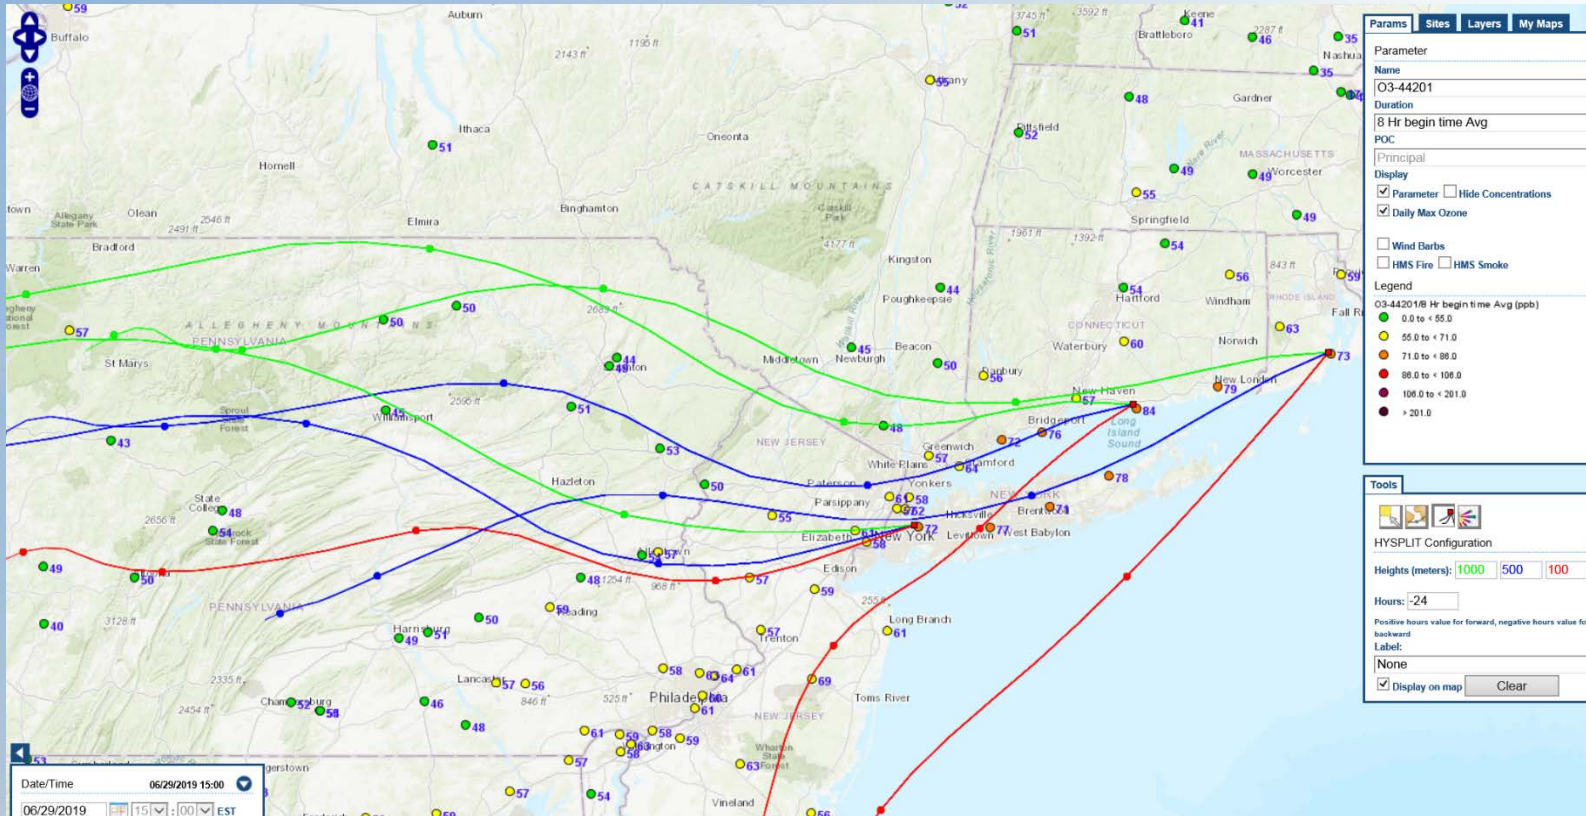

June 28, 2019 Back Trajectories

- Winds started out from the northwest, from a usually clean air region, but turned southwest, which advected ozone into coastal CT.

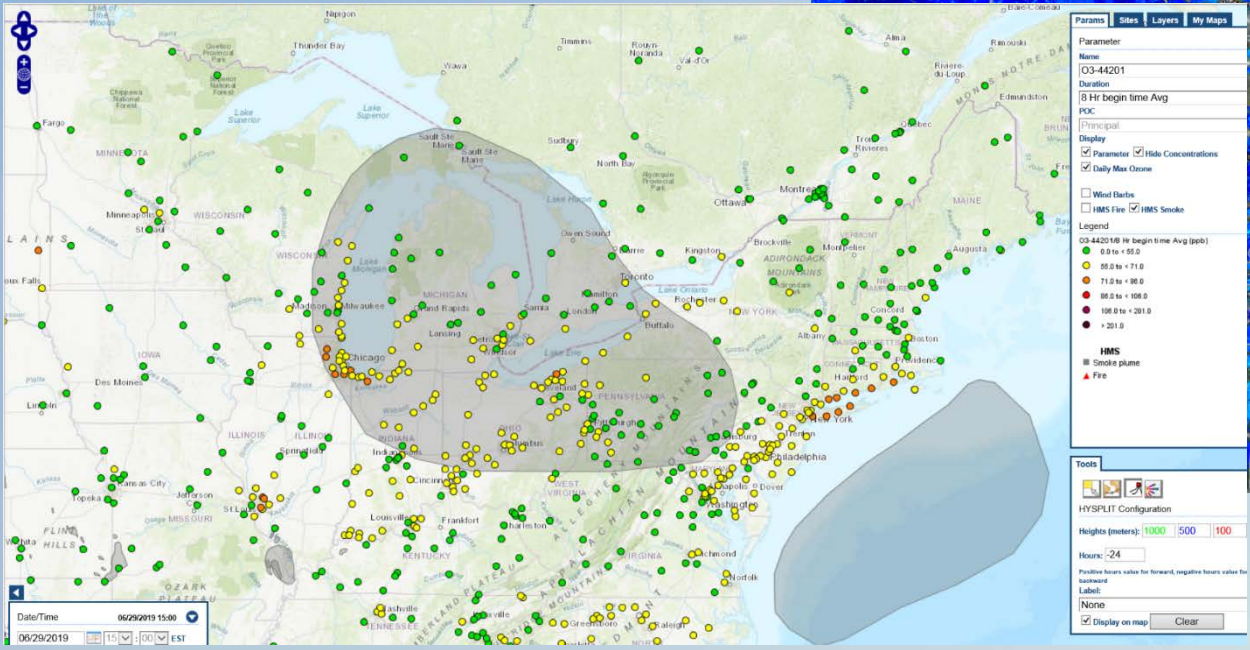

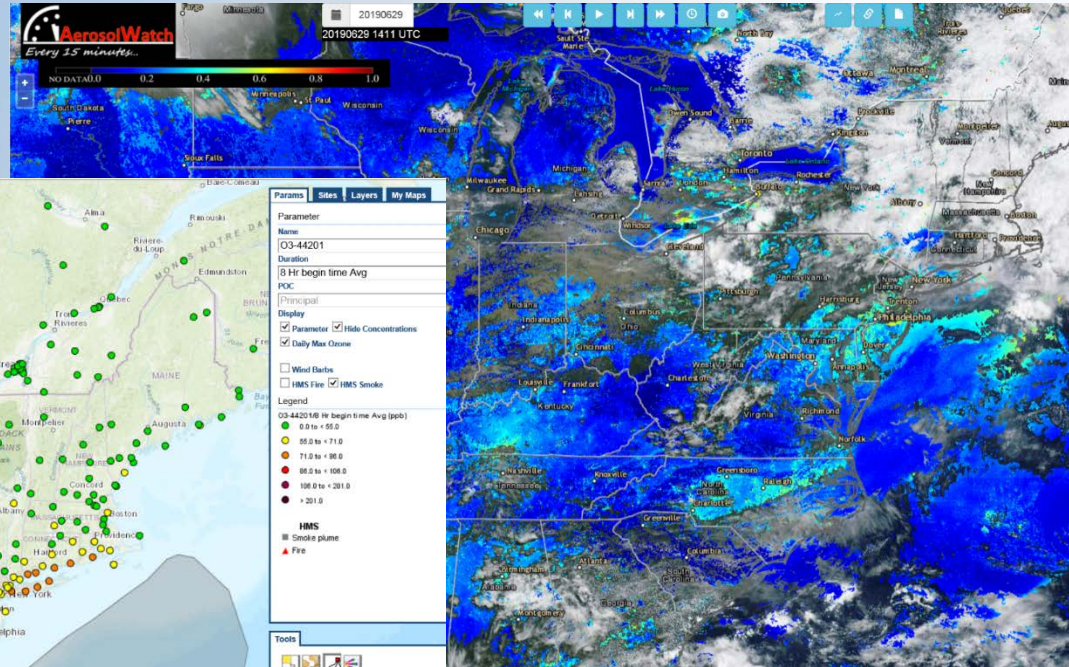

June 29, 2019 Back Trajectories

- By June 29th, a general west/southwest wind flow allowed pollutants from NYC and northern New Jersey to affect coastal CT.

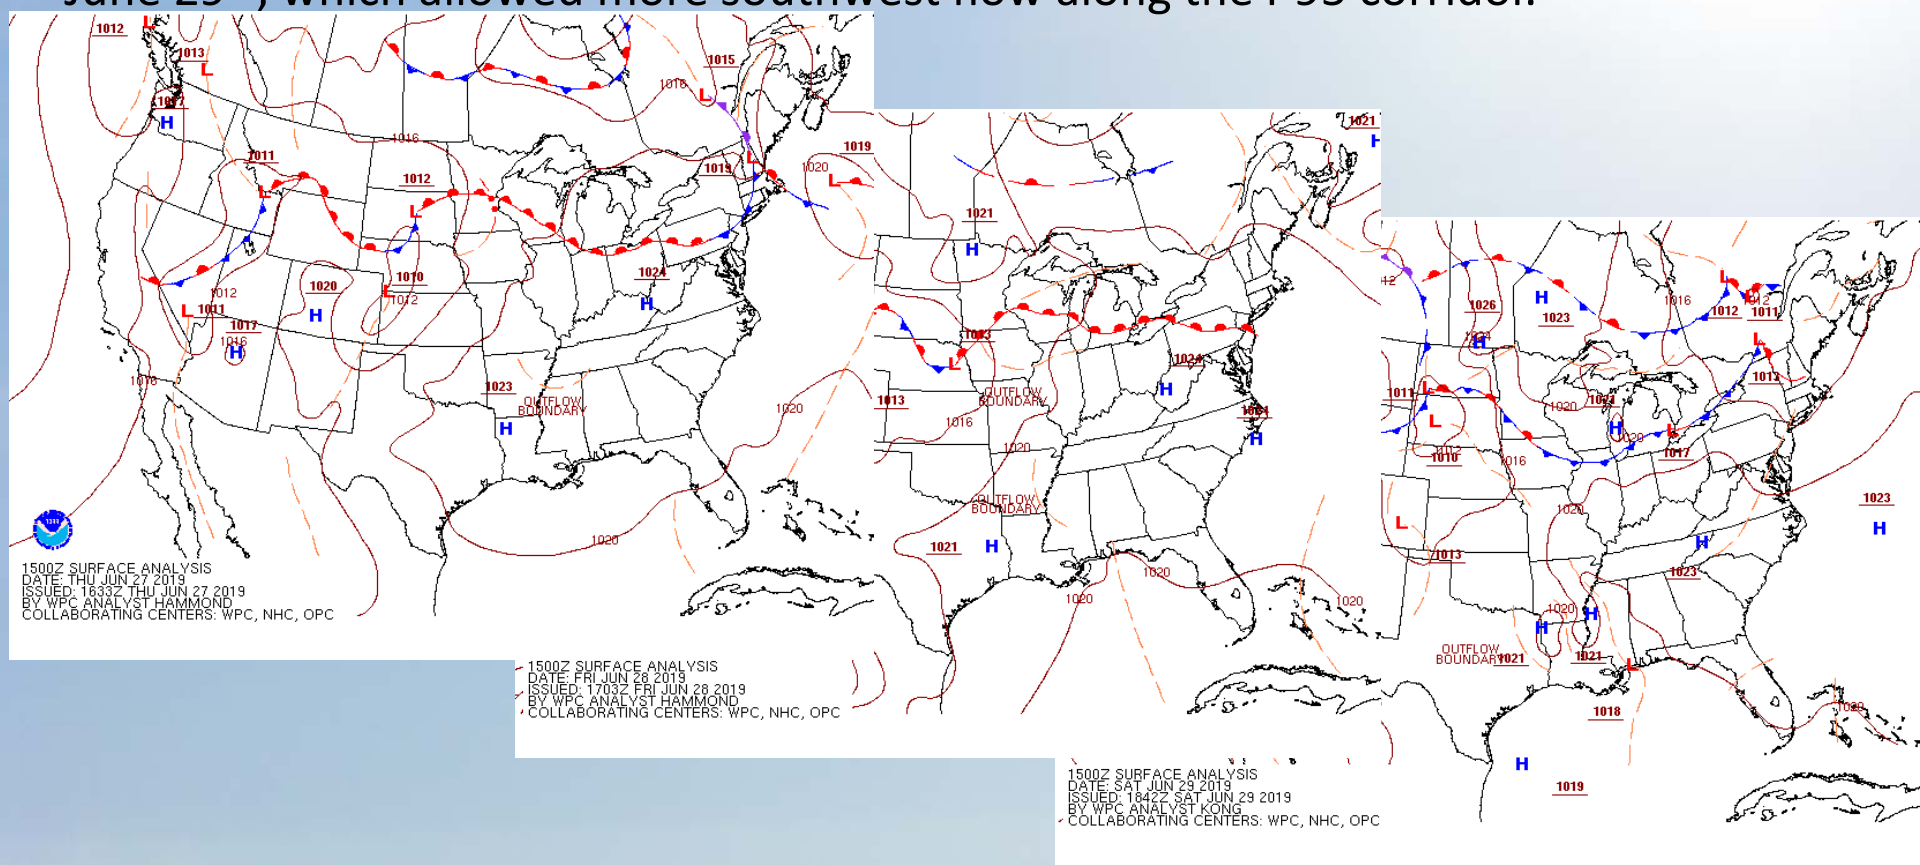

Aerosols detected by the Satellites

- A diffuse smoke plume was detected on June 29th, which may have elevated ozone levels during the event.

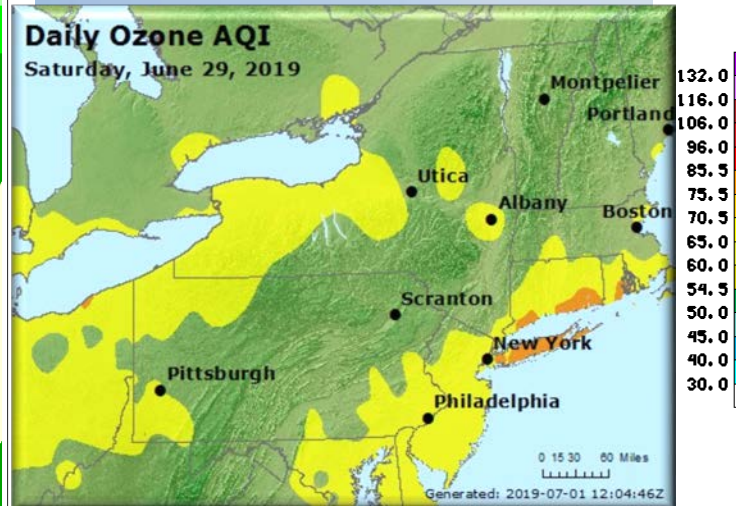

June 27-29, 2019 15z Surface Analysis

- Weak pressure gradients produced light surface winds. A 'lee' trough developed by June 29th, which allowed more southwest flow along the I-95 corridor.

June 29, 2019 Ozone Model runs

NAM V502 PROD BIAS COR DAY2 OZMX08 (PPB) 20190628 06Z

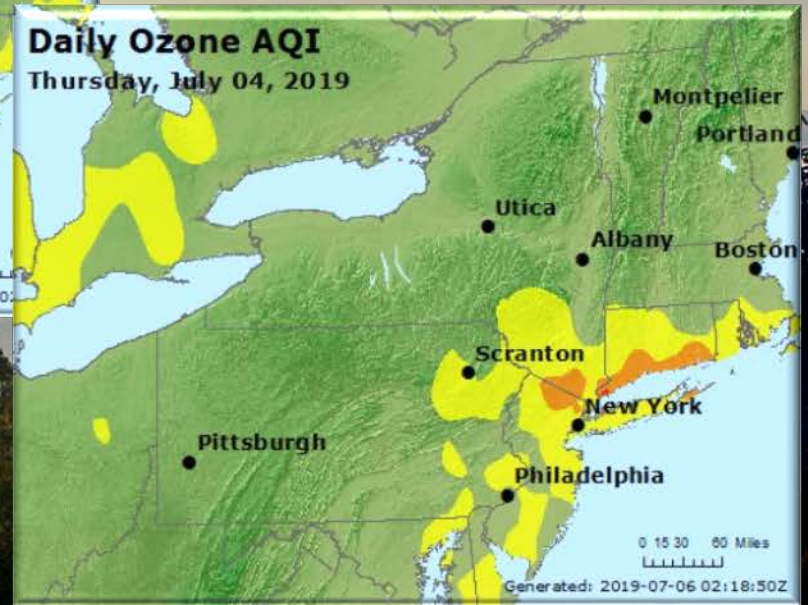

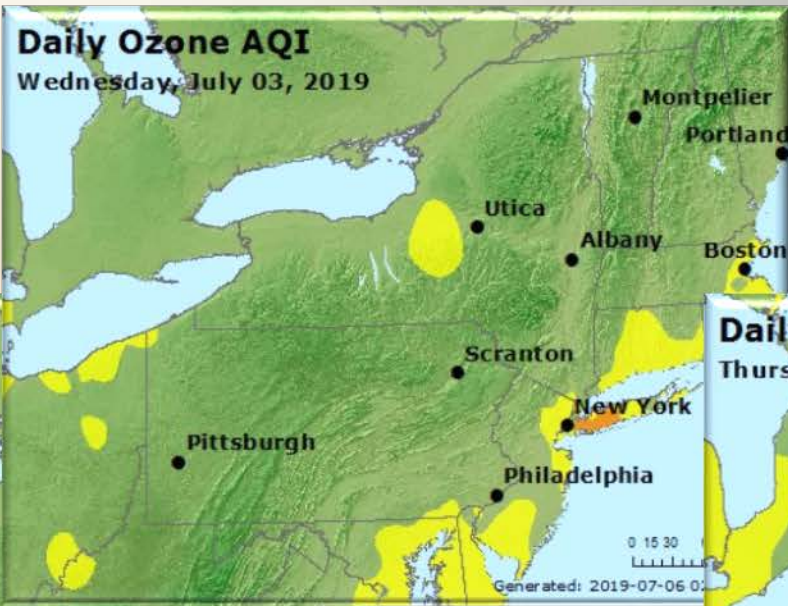

NAM V502 PROD DAY2 OZMX08 (PPB) 20190628 06Z CYC

- The NOAA June 28th day 2 model runs showed only moderate ozone (right), but the MAQSIP pushed the USG ozone into southeast CT.

Conclusion

- The NOAA production model generally performed better than the other models, but still tended to under-predict the ozone. The usually reliable NOAA bias-corrected version, under-predicted the ozone.
- Although smoke never appeared to be a factor at the time, it is possible that a diffuse plume was present that was difficult to detect from satellite images.
- Model differences, especially for June 29th, made it hard to forecast the magnitude of the event for Connecticut.

Ozone Event Analysis: July 4, 2019

Michael Geigert

July 4, 2019 Back Trajectories

- Surface winds were light from the northwest but recirculated late in the day. Smoke was modeled to stay to our north, but it appears that the 1000 meter winds may have transported this smoke back to the coast.

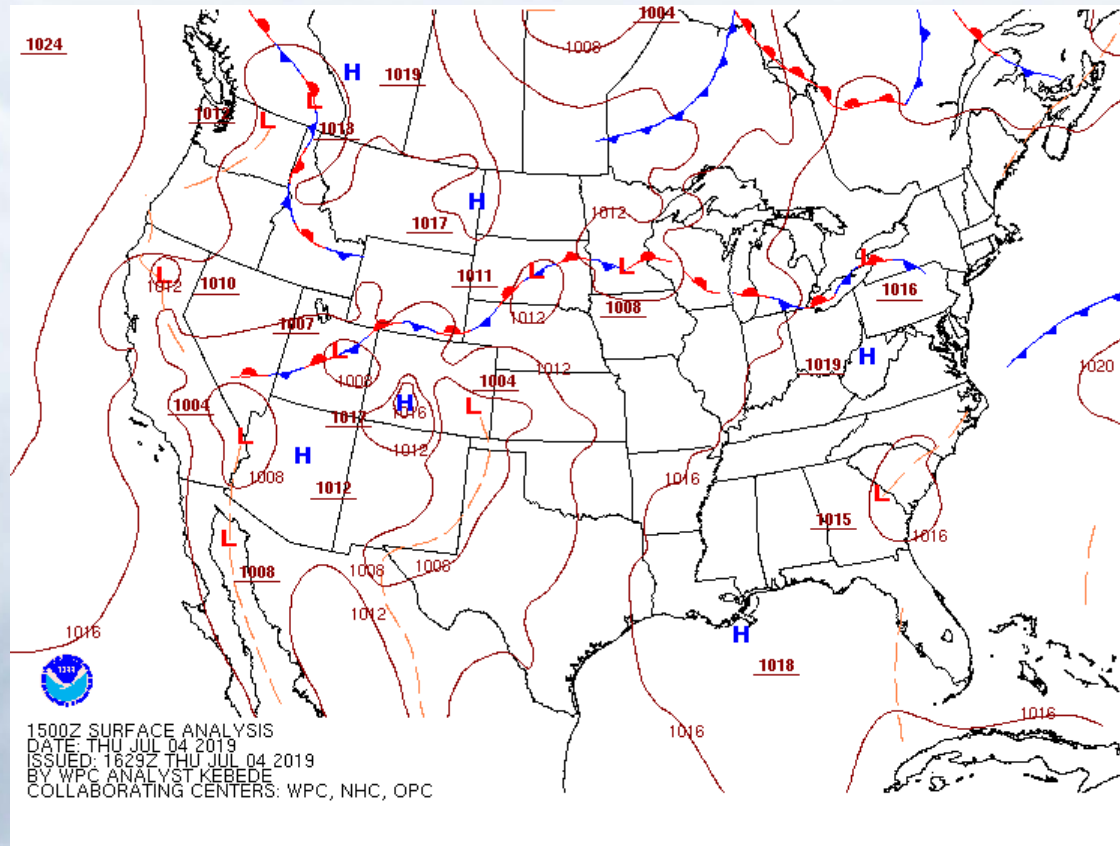

Aerosols detected by the Satellite

- A diffuse smoke plume was detected on July 4th, which may have elevated ozone levels during the event.

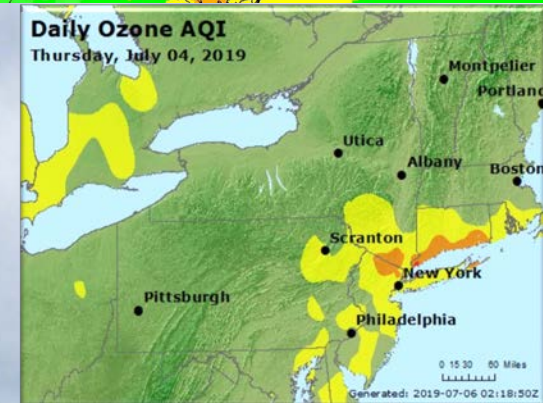

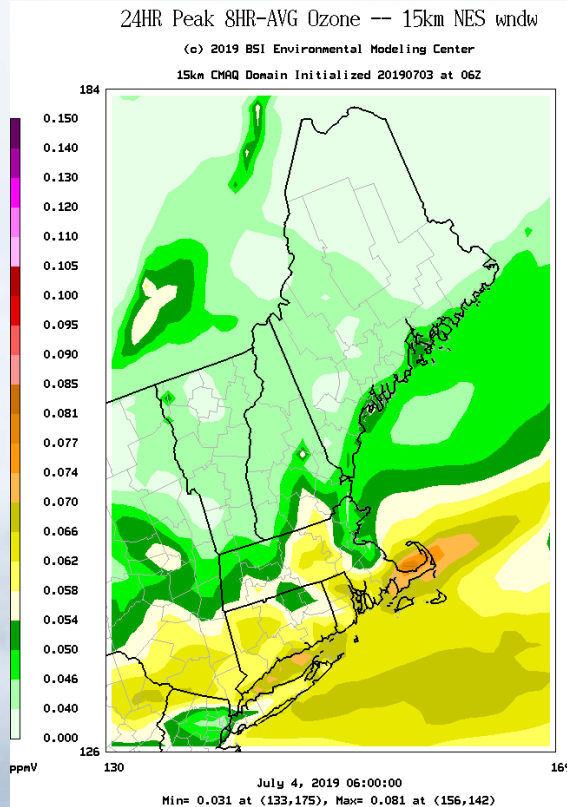

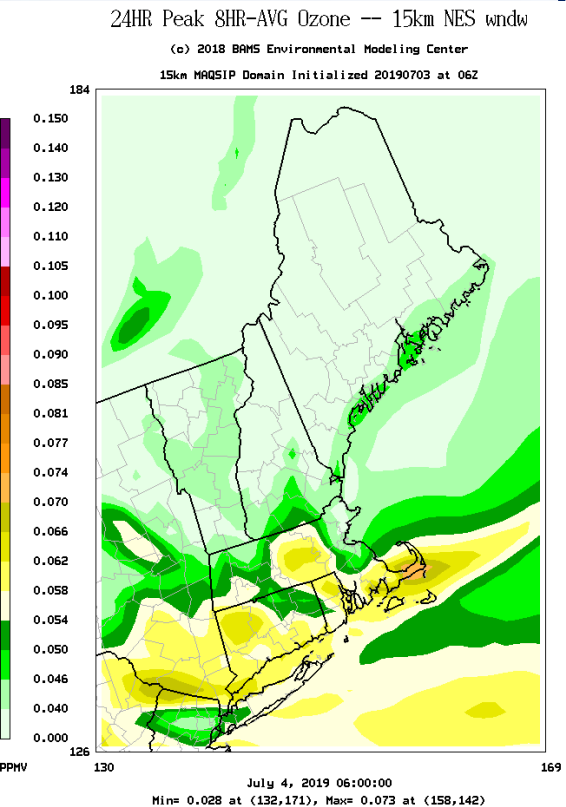

July 4, 2019 15z Surface Analysis

- Weak pressure gradients produced light surface winds.

July 3, 2019 Ozone Model runs

- The NOAA July 3, day 2 model run showed USG near the coast, as did the Barons CMAQ (center) but the MAQSIP (left) was only moderate. It is evident that the models under-predicted USG areas by 5-10+ ppb.

Conclusion

- Although the models suggested that a few coastal sites may have reached USG, they once again under-predicted the event.
- Although smoke was modeled to stay to our north, it appears likely that a diffuse plume was present and was recirculated into our coastal sites.
- It is sometimes the case that ozone levels can be lower on holidays with less commuting, so it was initially thought that the models may be on the high side. The models did not take any smoke emissions into account, which likely biased the predicted ozone concentrations too low.

- Eight Connecticut monitors exceeded the 70 ppb NAAQS
- Four monitors had Unhealthy Air Quality

July 16, 2019 Hourly Ozone

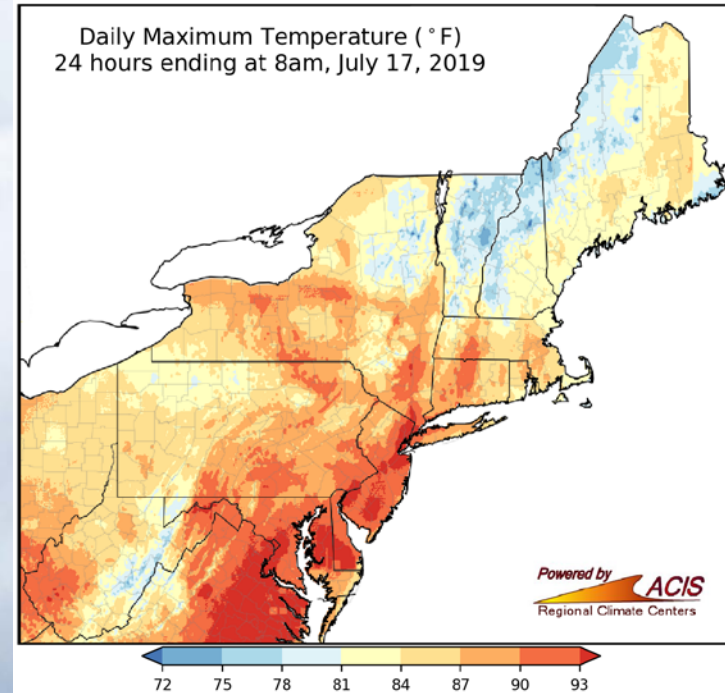

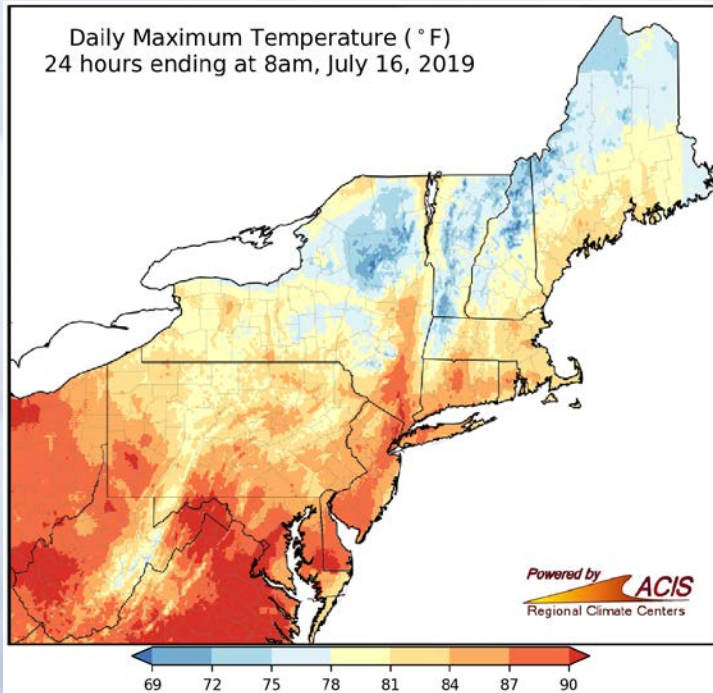

July 16, 2019 Hourly Ozone in Connecticut

- Eight monitors exceeded the NAAQS 70 ppb standard, with Middletown reaching a high of 116 ppb.

Maximum 24-hr Temperature

- From 8 AM on July 16 to 8 AM on July 17, maximum temperatures reached 94 degrees in parts of the state.

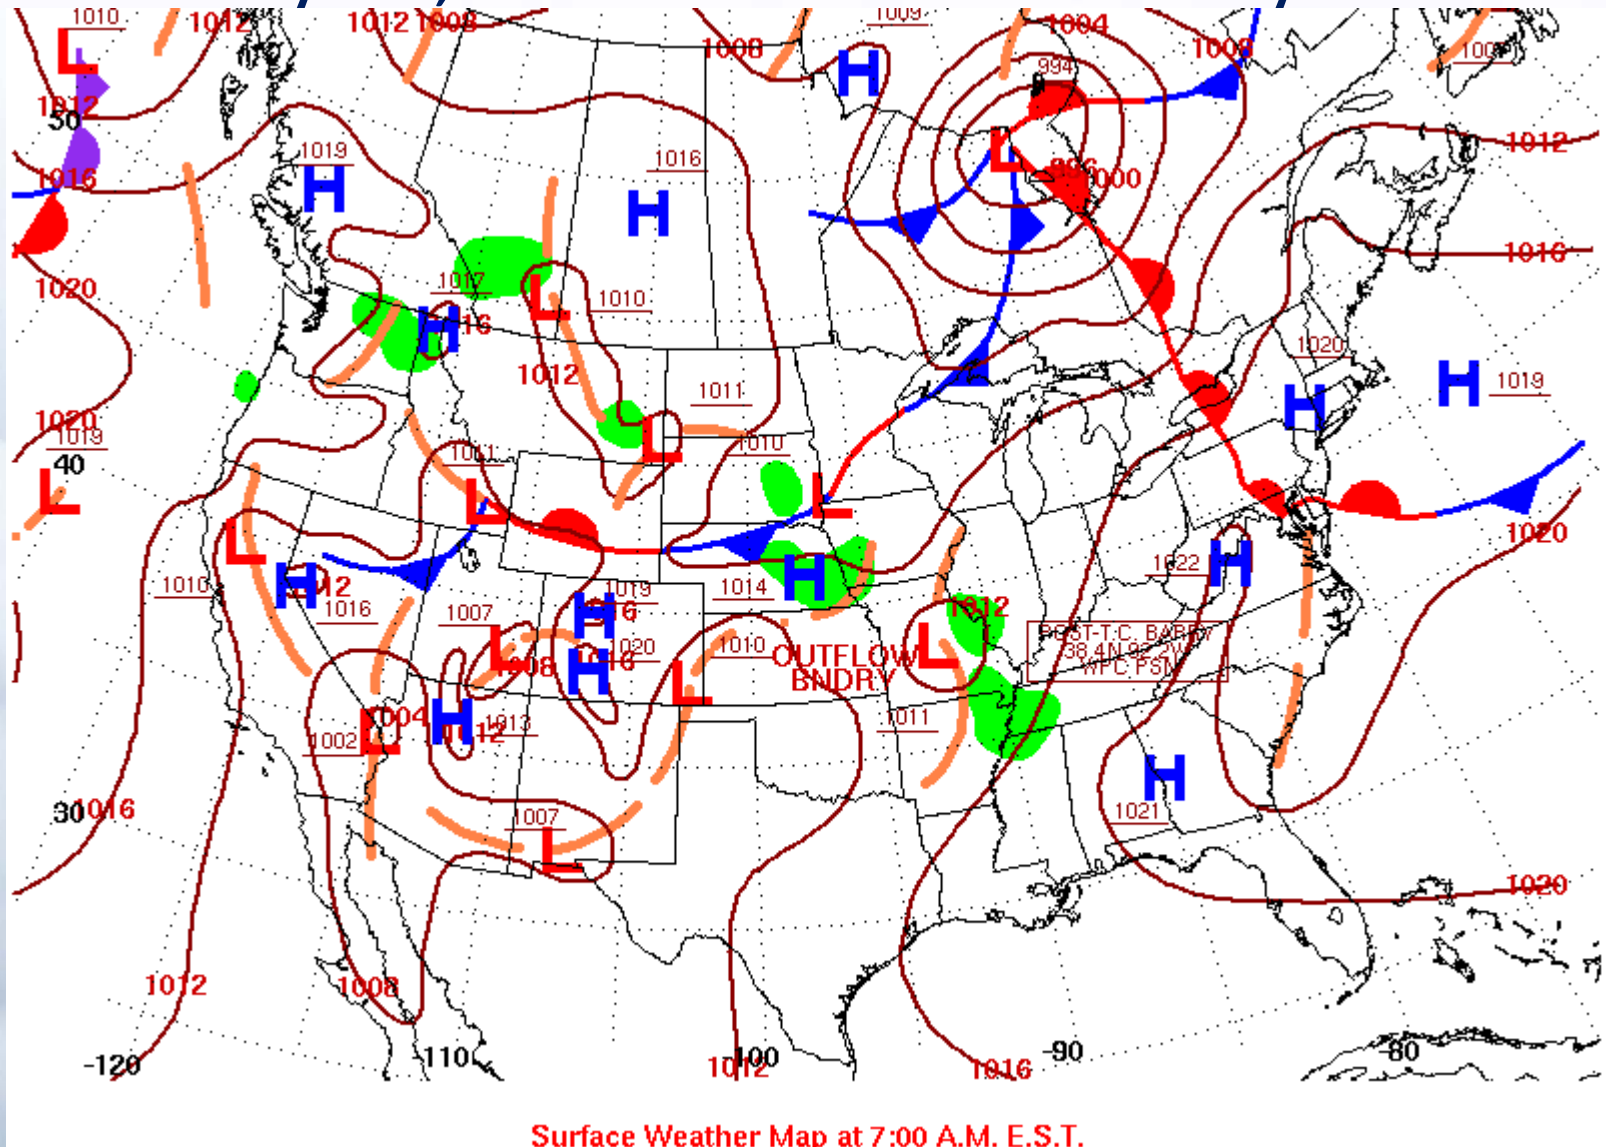

- These warmer temps were conducive to ozone production.

July 16, 2019 Back Trajectories

- 24 hour back trajectories from 4:00 PM EST
- The lowest back trajectory (red) goes over the Long Island Sound, which provided precursors for ozone production from the New York Metropolitan area and Long Island.

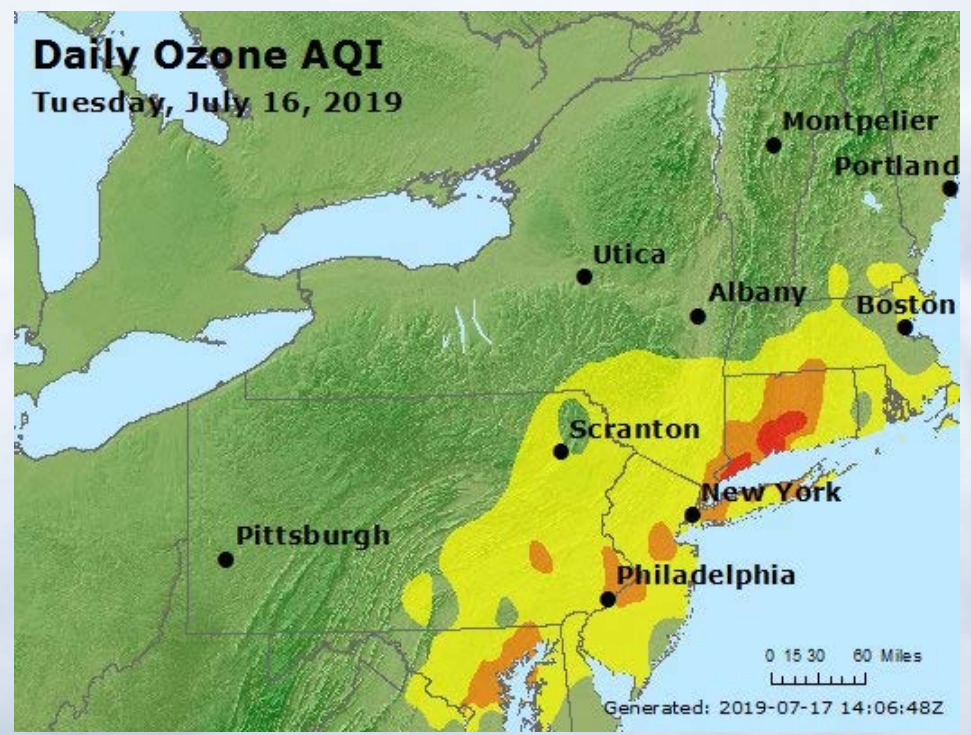

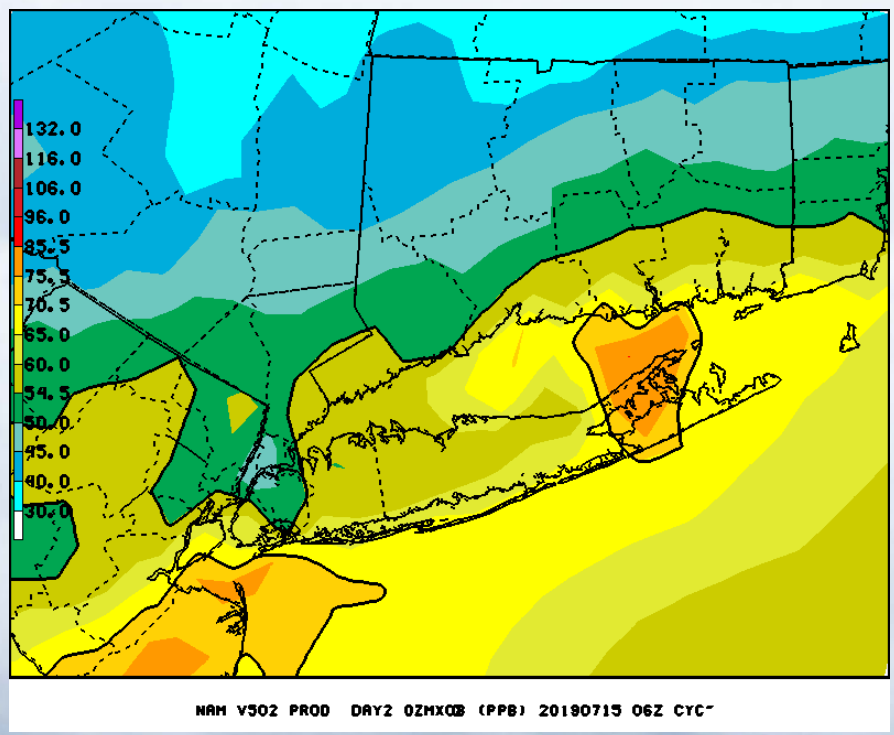

July 16, 2019 12z Surface Analysis

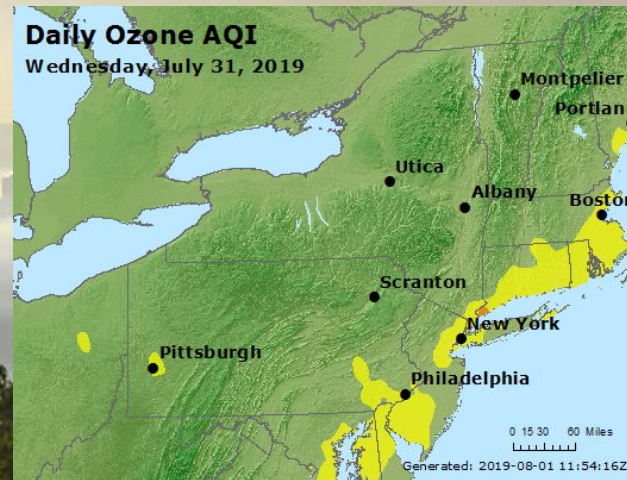

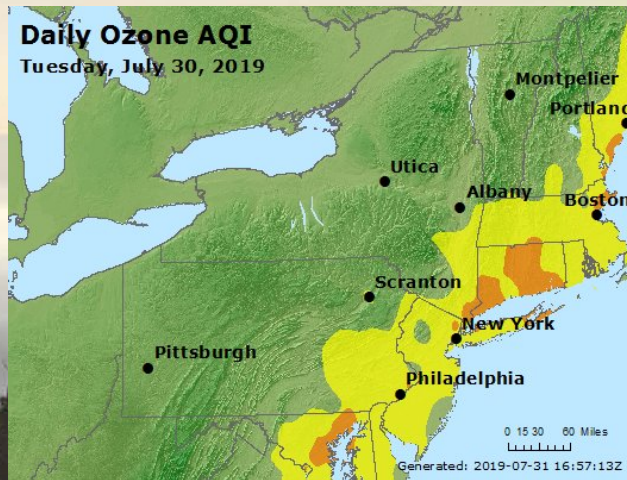

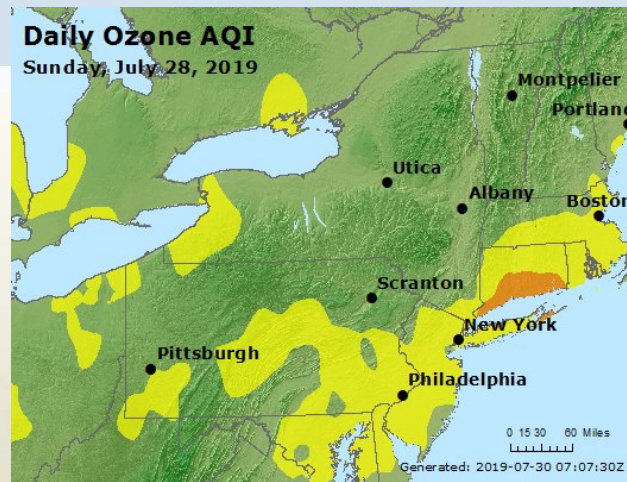

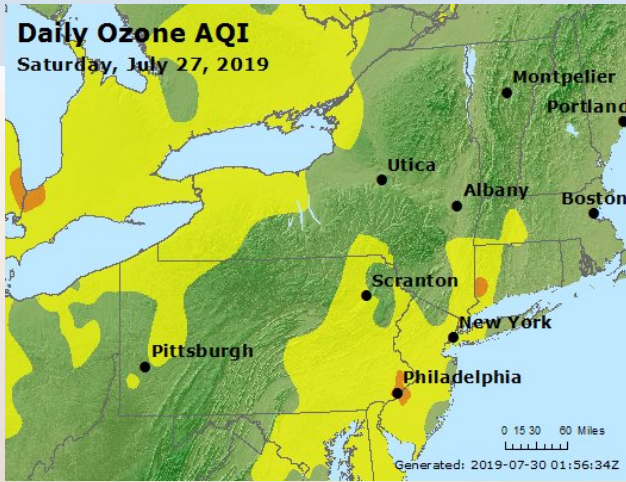

- High pressure was present over CT which contributed to calm winds.

July 15, 2019 Ozone Model Runs (NOAA)

- The NAM-CMAQ July 15 day 2 model run shows good ozone levels in most of the state and moderate levels across the coastal regions.

Ozone Event Analysis: August 30, 2019

Daniella Lopez

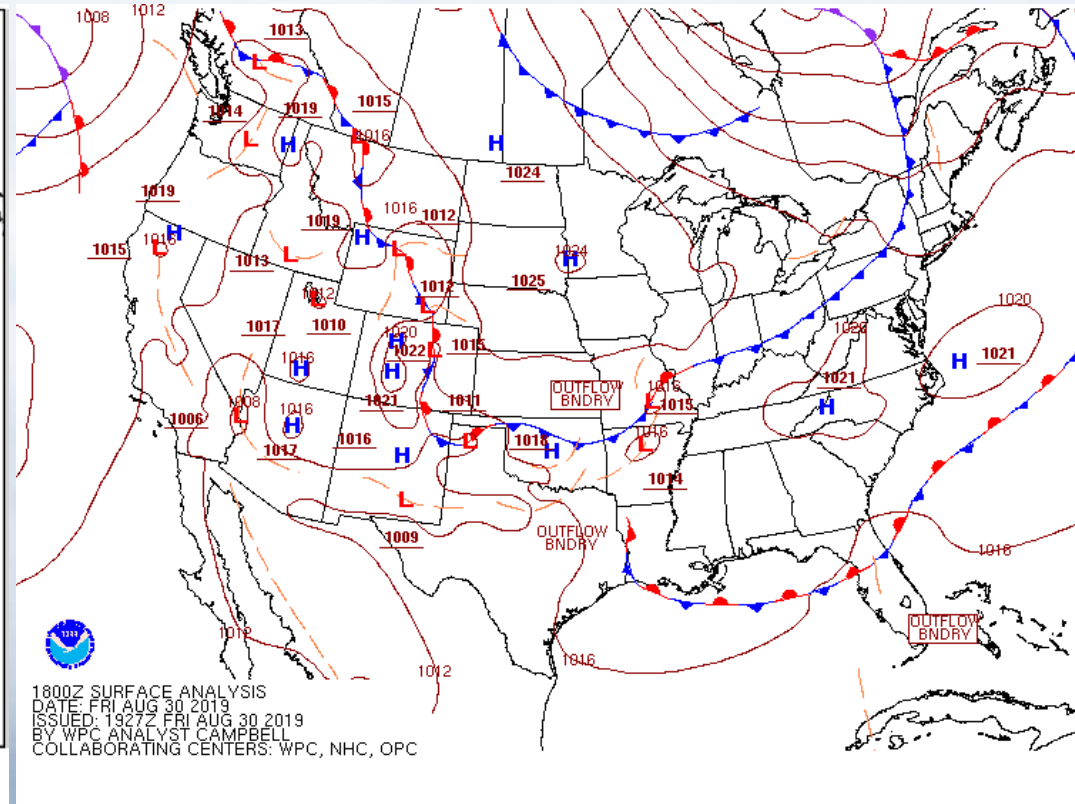

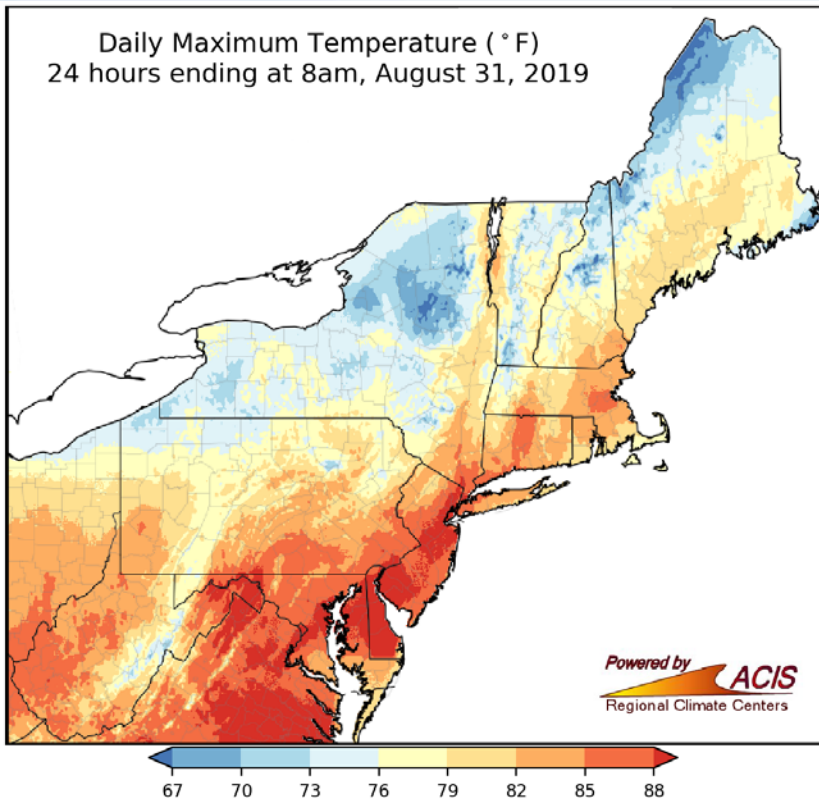

August 30 Hourly Ozone in CT

- Seven monitors exceeded the 70 ppb NAAQs.
- Middletown peaked at 94 ppb, being the highest hourly ozone value for the day.

August 30 Maximum 24-hr Temperature

- Most of CT reached temps in the mid 80's with the max being 86°F

August 30, 2019 18z (2:00 pm EST) Surface Analysis

August 30, 2019 Back Trajectories

- 24 hour back trajectories for the Middletown monitor show air coming from the NYMA and LIS.

August 30, 2019: NO₂ 18GMT (2pm)

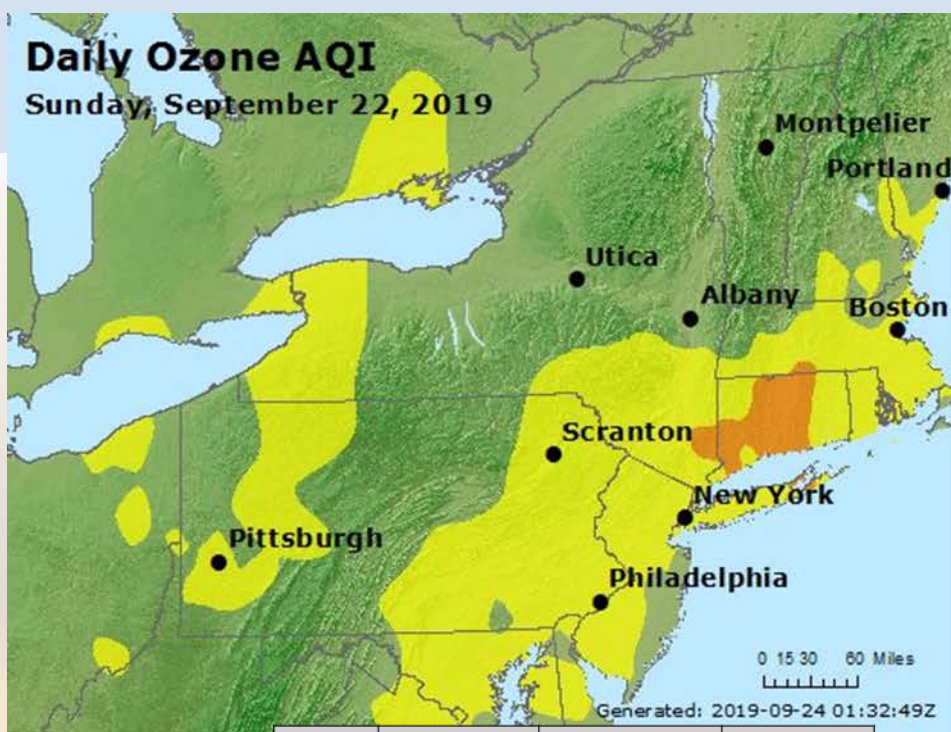

- A highly concentrated plume of NO₂ can be seen over the NYMA extending to the exceeding monitors. The plume is transported into CT along the SW winds.

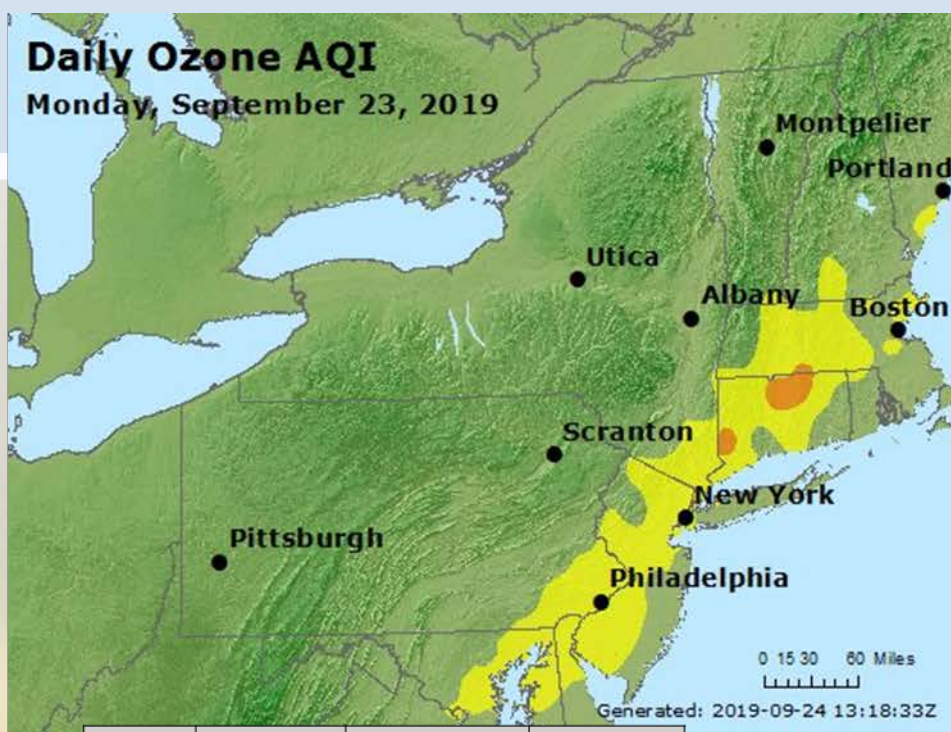

Conclusion

- A large NO₂ plume was present over NYMA and extended into CT aligning with the exceeding monitors.
- NO₂, warm temperatures (86°F) and a SW wind for most of the afternoon were conducive to ozone formation and transport.
- The models for August 30, 2019, did not forecast USG within CT.
- The Barons CMAQ and MAQSIP models under-predicted USG, however, the moderate levels were accurate in both.
- The NAM-CMAQ model predicted USG close to the coast of CT. This model was the most accurate.

Ozone Event Analysis: September 22-23, 2019

Kristin Salimeno

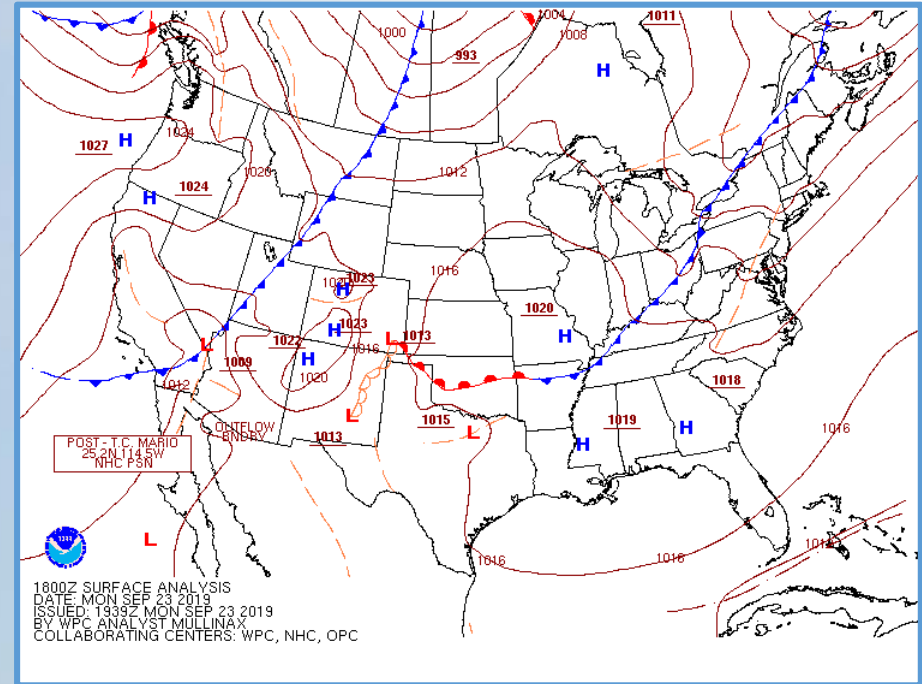

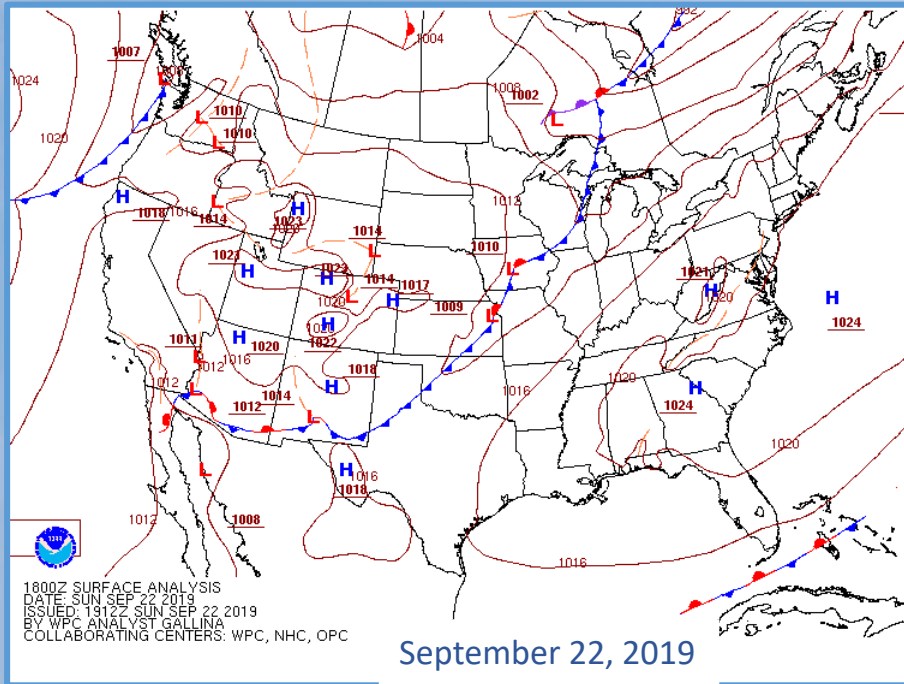

September 22-23 Maximum 24-hr Temperature

- On September 22 (left), temperatures in the 80's were measured along the SW coastline and up through the middle of the state. Lower temps were measured in the NW and NE corners of the state.

- On September 23 (right), temperatures increased across the state, with the middle portion of CT reaching close to 90. The lowest temperatures were recorded in the SE corner of the state.

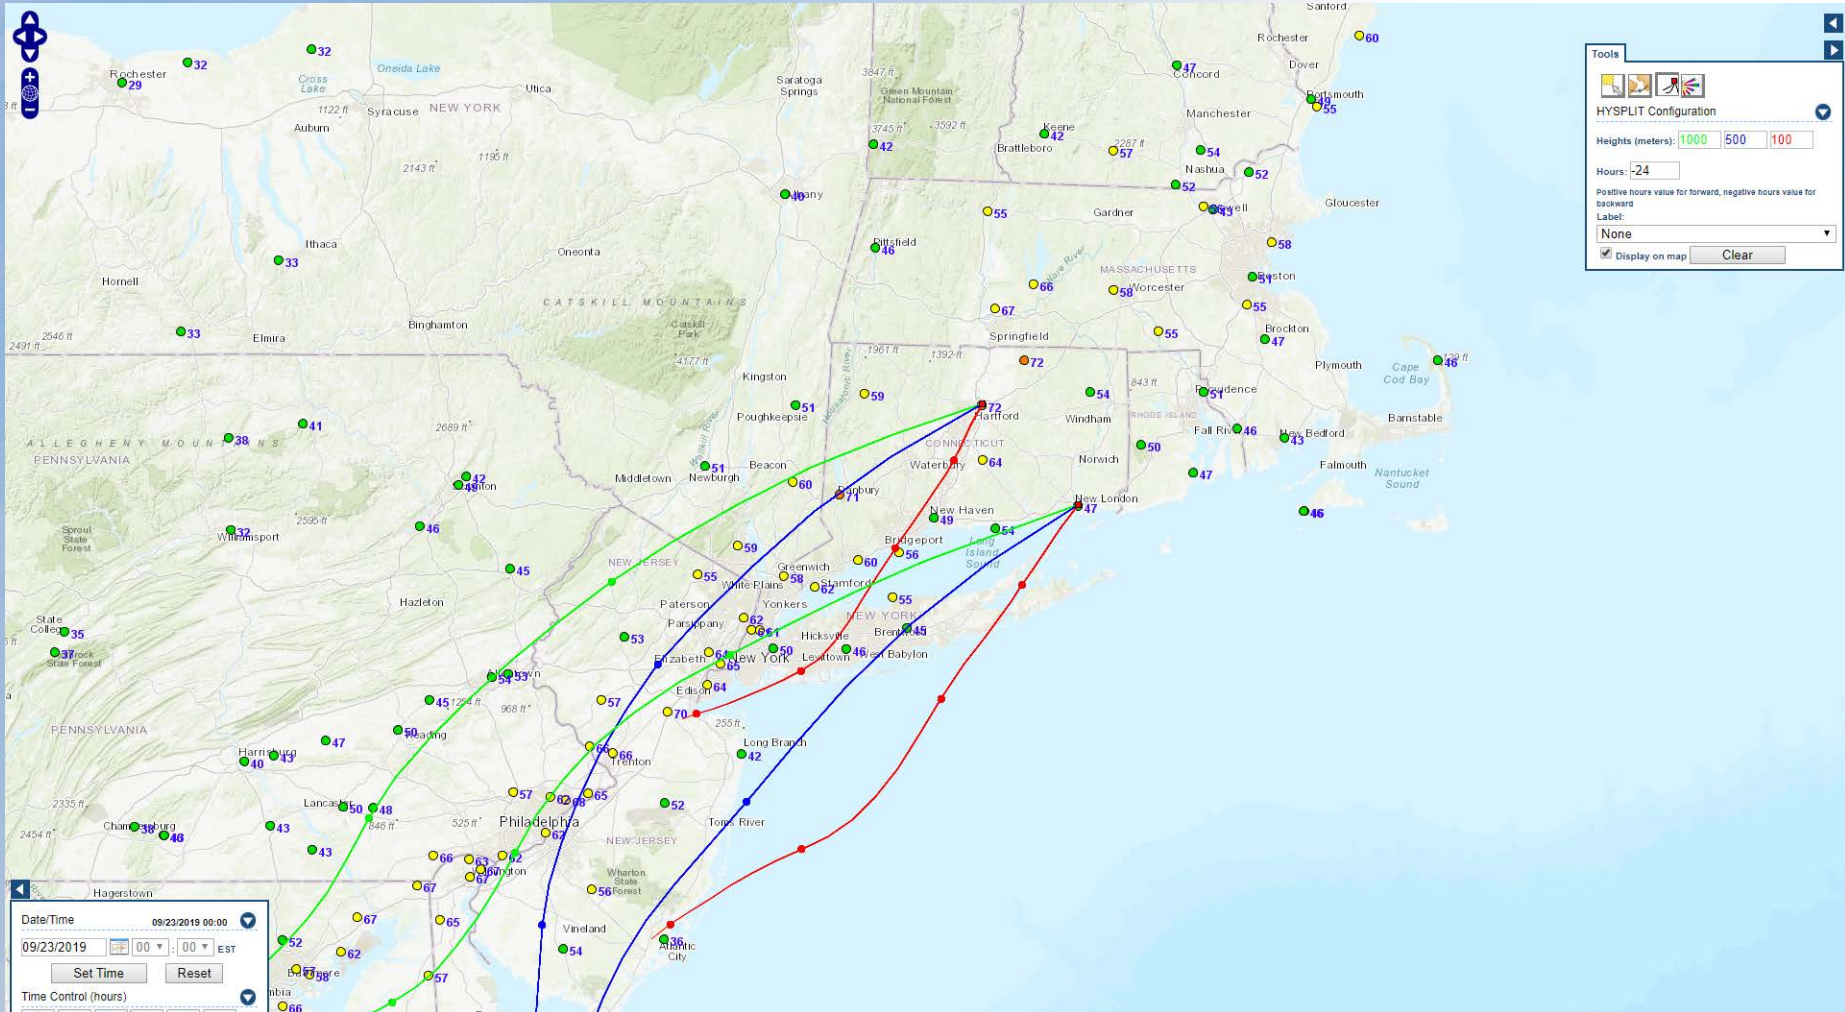

September 22-23, 2019 18z Surface Analysis

- Conditions over CT were calm and clear for September 22 and 23.

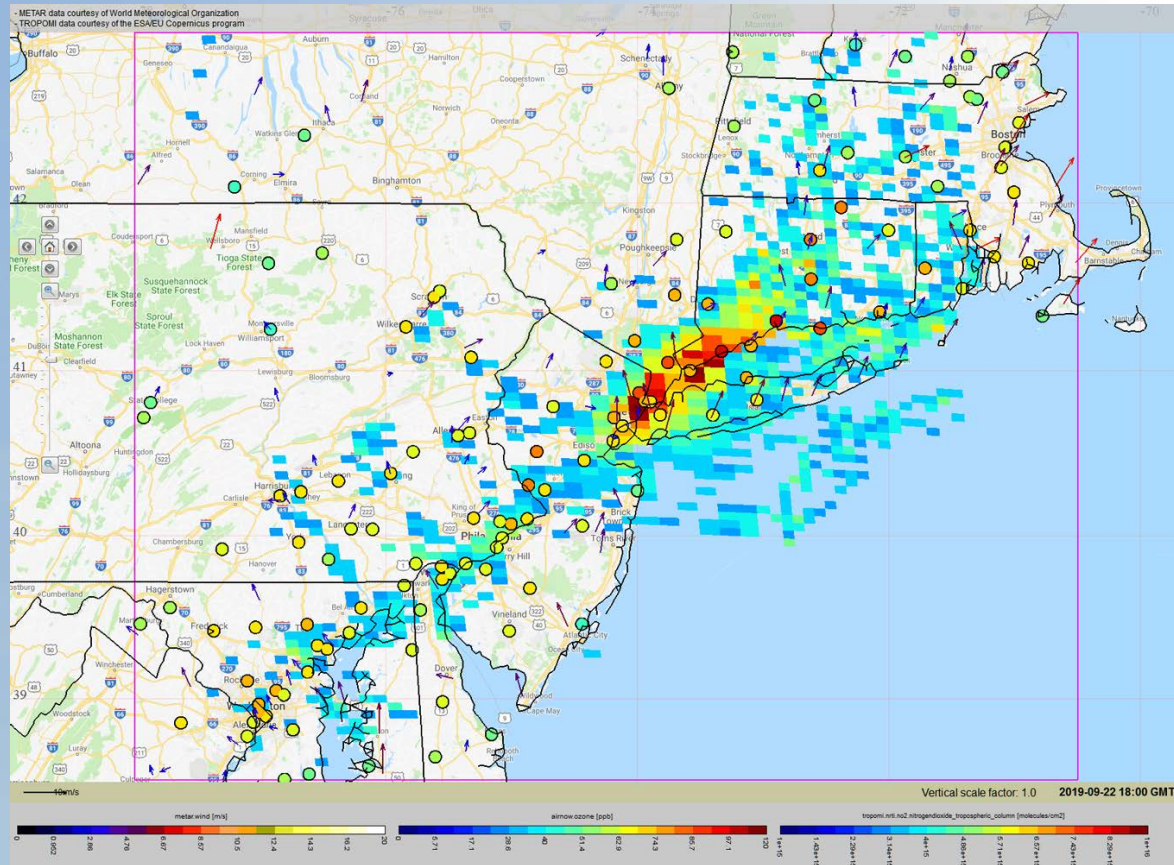

September 23, 2019 Back Trajectories

- 24 hour back trajectories for the East Hartford monitor show air coming from over the NYMA.

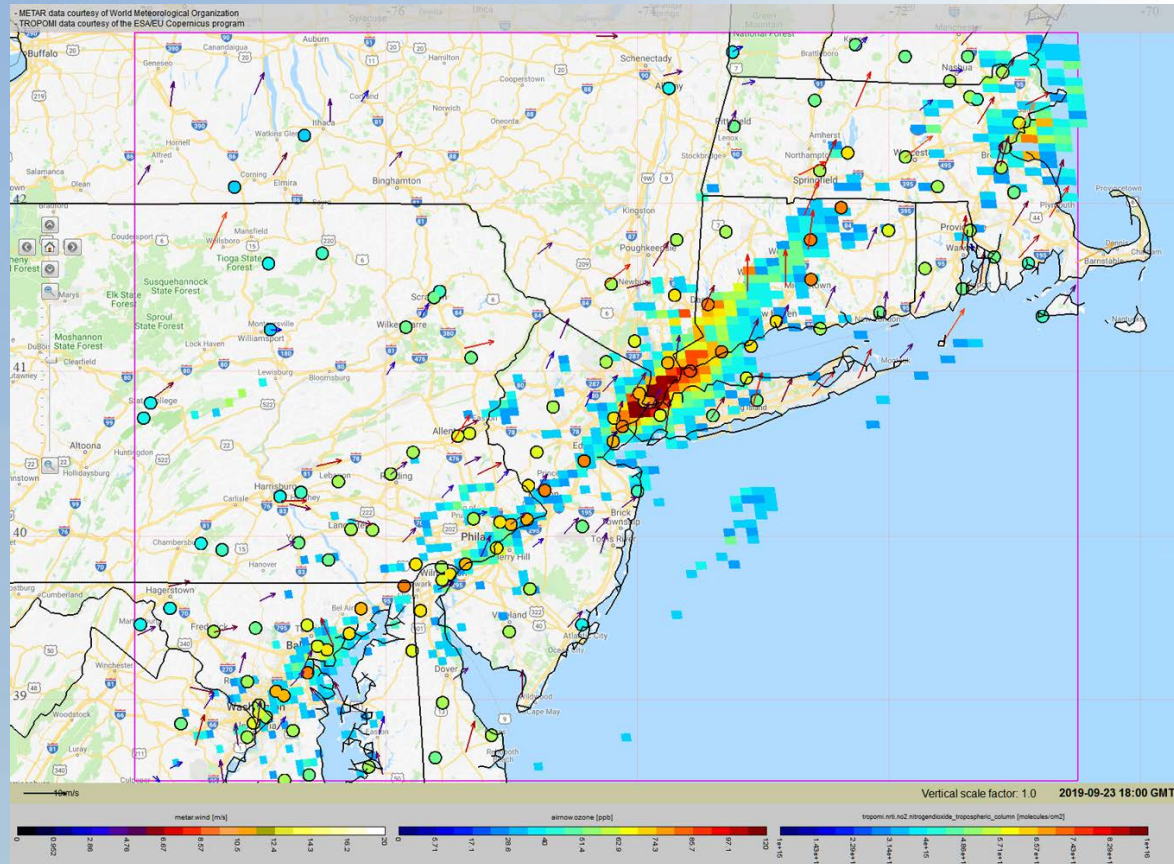

- 24 hour back trajectories for the Groton monitor show air passed over Long Island and LIS.

September 22, 2019: TROPOMI NO₂, METAR Wind Vectors, and AirNow Ozone Data 18GMT (2:00 pm EST)

- The NO₂ plume is transported along the SW coast of CT and into the middle portion of the state.
- Wind vectors show a SW wind.

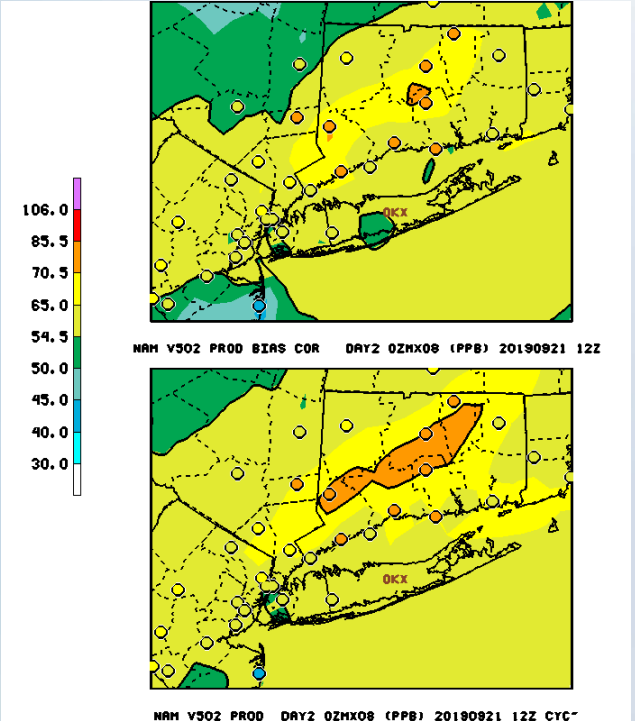

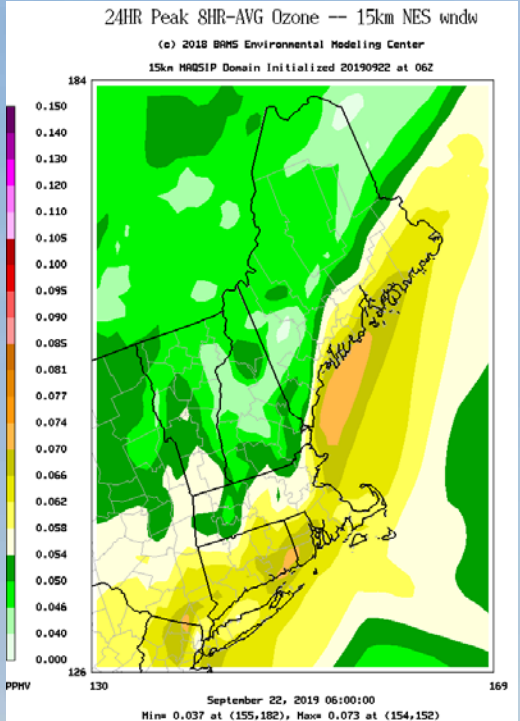

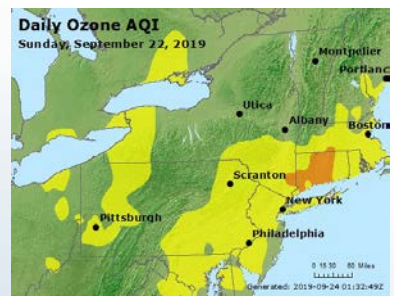

September 23, 2019: TROPOMI NO₂, METAR Wind Vectors, and AirNow Ozone Data 18GMT (2:00 pm EST)

- The SW wind transports the NO₂ plume into CT.

September 22, 2019 Model Performance

- The NAM-CMAQ (right) and the Baron's MAQSIP (right) model forecasted spots of USG. The NAM-CMAQ non-biased corrected model forecasted the largest area of USG.

2019 Conclusions

- 21 exceedance days in 2019, compared with 23 in 2018;
- Typical warm, dry, summer weather pattern set up from late June through August, pushed the highest ozone levels from high NOX and VOC emissions along the I-95 corridor and NYC into Connecticut because of SW wind pattern in 2019 (25 days of 90+ degrees) vs. 2018's South wind pattern (32 days of 90+ degrees);
- The NOAA & Barons models generally under predicted in May and early June, and again in September, and
- Some over predictions began in late June and continued into late August, however there were some days of under predictions as well.

2019 Conclusions

- When we know that NOAA/BARONS models are over predicting, we generally lower the ozone levels by as much as 10-20 ppb; however in some instances we predicted a bit to low (an additional 3-5ppb) forecasting ozone levels below the NAAQS (USG AQI);
- We also under-predicted when smoke was present for a few events this summer based on the modeling. Smoke may have hindered the model performance due to solar attenuation; therefore models may have under-predicted an additional 5-10ppbs, and
- On-going but limited Long Island Sound Ozone Study (LISTOS) continue to provide more insight and tools to Forecasters for increasing the forecast skill in future.
